# 1 The Service Layer

Since EFS 8.1, the new Service Layer allows to access EFS key functionalities from outside EFS. Thus, applications relying on EFS data and functionalities can be created outside EFS with quite different technologies.

QuestBack customers profit from the new infrastructure in many respects:

- The spectrum of Customizing Solutions offered by QuestBack is extended, regarding both the available functionalities and the technologies that can be used.
- The Service Layer opens up new possibilities for customers who wish to connect to EFS
  with their own applications or who wish to integrate EFS into their own applications.

The scope of functionality in brief:

- From EFS 9.1, the Service Layer covers the scope of functionality of the old SOAP services. More key functionalities of EFS will be made available step by step in future releases. Future EFS functions which are of interest to customers will be made available as well.
- The services can be called from outside via HTTP or HTTPS.
- Various data exchange formats can be used (e.g. JSON).

Configuring the Services Page 4 of 10

# 2 Configuring the Services

A dedicated configuration menu allows to view and configure the services which are available on your EFS installation.

- The menu is in **Options**-> **Services**->**Service configuration**.
- The menu has the same design as the menu for the familiar SOAP services (Options-> Services-> Web services).
- The **Service configuration** menu is only available if QuestBack Support has activated usage of services for your installation. To view and access the menu, you need either read rights for the ACL right "webservice\_conf" or membership in the root team.

The following steps are necessary to use a specific service:

- QuestBack Support has to add the service.
- The service must be activated. If necessary, the button Activate all services allows to
  activate all services available on the installation en bloc.
- The staff account used to access the service is allocated to a specific staff team. This staff
  team must have the necessary access rights to the service. Access rights to individual
  services can be assigned on the tab **Access groups**.
- Furthermore, many services include a check for object rights. To use survey.questionnaire.createPage or survey.questionnaire.deletePage, for example, the staff team needs write rights for the target project.
- All calls are logged on the Access log tab. The entries can be searched by IP address, name of the admin account used, service name and date.

## 3 Accessing the Service Layer

### 3.1 Access Modes

The service layer offers two access modes:

- Description: In this modus, the service layer will describe itself. In SOAP format, for example, a WSDL will be generated and delivered. This modus allows clients to find out which services are provided and which parameters they have
- Transaction: In this modus, a service method is called and executed.

How you address these modes depends on the format handler used.

### 3.2 Format Handler

Currently the service layer supports HTTP/HTTPS and three internal formats:

- PHP-serialized: Here, the input and output parameters are transferred as serialized
   PHP arrays. This is the recommended approach for PHP clients.
  - o To activate the handler, use the URL parameter "handler" with the value "php".
  - The name of the invoked method is handed over in the URL parameter "method". The method name is structured as follows: MODU-LENAME.ACTORNAME.METHODNAME (separator: periods).
  - If the request is an HTTP GET request, the description mode will be triggered.
     Otherwise, the transaction mode will be used.
- JSON: Data are transferred in JSON encoding. See the example below.
  - o To activate the handler, use the URL parameter "handler" with the value "json".
  - The name of the invoked method is handed over in the URL parameter "method". The method name is structured as follows: MODU-LENAME.ACTORNAME.METHODNAME (separator: periods).
  - If the request is an HTTP GET request, the description mode will be triggered.
     Otherwise, the transaction mode will be used.
- SOAP: SOAP is used to transfer data. See the example below.
  - o To activate the handler, use the URL parameter "handler" with the value "soap".

- The name of the invoked method is handed over in the URL parameter "method". The method name is structured as follows: MODU-LENAME\_ACTORNAME\_METHODNAME (separator: underlines \_).
- If the URL parameter "wsdl" is set in the request, the description mode will be triggered and a WSDL will be generated. Otherwise, the transaction mode will be used.

### 3.3 Authentication

Two authentication methods can be used:

- Tokens: QuestBack Support can provide tokens for you and your staff members. These
  tokens can be used for authentication when invoking a service (parameter name: "token").
- Account name and password for the EFS admin area: The easiest authentication method, as any staff member with admin area access already owns an account. But please mind: When calling the services via http, account name and password will be transferred unencrypted, i.e. it is possible to log them e.g. on proxies and use them to access the admin area. Therefore, QuestBack recommends to use tokens or to call the services via SSL.

### 3.4 Calling the Service Description

Self-description of the PHP handler:

http://your-domain.com/service/?handler=php

#### Calling the WSDL:

http://your-domain.com/service/?handler=soap&wsdl=1

Please note: The new service layer allows to configure access rights individually for each service and each staff team. Therefore, when accessing the service layer, you will now find a dynamic list of services. There is no central WSDL file anymore, instead the WSDL file will be generated dynamically each time someone invokes the services according to that person's access rights. That way, the invoking users will see a WSDL for the very services they are allowed to use.

### 3.5 Important Parameters

These are the most important parameters:

- handler: name of the format handler (php, json, soap).
- method: name of the called method for PHP and JSON handler.
- version: optionally-used version number of the Service API.
- token: contains the token for authentication.
- wsdl: generates the WSDL if the SOAP handler is used.

### 3.6 Examples

### **Example: JSON call with http authentication**

```
/**
* Please adapt
**/
$baseUrl="http://your.server.name/";
$userName="user1";
$passwd="topsecret";
/* *********************************
* if necessary please adapt
*/
set_include_path(get_include_path().':'.dirname(__FILE__).'/../wcp/3rd/');
/* *************************
require 'Zend/Http/Client.php';
$call = array('method'=>'efs.system.getLoad','params'=>array());
$url=$baseUrl."service/index.php?handler=json";
```

```
$client=new Zend_Http_Client();
 $client->setUri($url);
 $client->setAuth($userName,$passwd);
 $client->setMethod(Zend_Http_Client::POST);
 $client-
 >setRawDa-
ta(json\_encode(array('method'=>\$call['method'],'jsonrpc'=>'2.0','id'=>1,'params'=>\$call['method'],'jsonrpc'=>'2.0','id'=>1,'params'=>\$call['method'],'jsonrpc'=>'2.0','id'=>1,'params'=>\$call['method'],'jsonrpc'=>'2.0','id'=>1,'params'=>\$call['method'],'jsonrpc'=>'2.0','id'=>1,'params'=>\$call['method'],'jsonrpc'=>'2.0','id'=>1,'params'=>\$call['method'],'jsonrpc'=>'2.0','id'=>1,'params'=>\$call['method'],'jsonrpc'=>'2.0','id'=>1,'params'=>\$call['method'],'jsonrpc'=>'2.0','id'=>1,'params'=>\$call['method'],'jsonrpc'=>'2.0','id'=>1,'params'=>\$call['method'],'jsonrpc'=>'2.0','id'=>1,'params'=>\$call['method'],'jsonrpc'=>'2.0','id'=>1,'params'=>\$call['method'],'jsonrpc'=>'2.0','id'=>1,'params'=>\$call['method'],'jsonrpc'=>'2.0','id'=>1,'params'=>\$call['method'],'jsonrpc'=>'2.0','id'=>1,'params'=>\$call['method'],'jsonrpc'=>'2.0','id'=>1,'params'=>\$call['method'],'jsonrpc'=>'2.0','id'=>1,'params'=>\$call['method'],'jsonrpc'=>'2.0','id'=>1,'params'=>\$call['method'],'jsonrpc'=>'2.0','id'=>1,'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=>\$call['method'],'params'=\tall['method'],'params'=\tall[
params'])));
 $response=$client->request();
 /**
   * Get JSON result
   */
 $return=$response->getBody();
Example: SOAP call with http authentication
   * Please adapt
   **/
 $baseUrl="http://your.server.name/";
 $userName="user1";
 $passwd="topsecret";
 ini_set("soap.wsdl_cache_enabled",0);
ini_set("default_socket_timeout",10);
 /**
   * if necessary please adapt
   */
```

```
set_include_path(get_include_path().':'.dirname(__FILE__).'/../wcp/3rd/');
$call = array('method'=>'efs.system.getLoad','params'=>array());
$client = new SoapClient($baseUrl."service/index.php?handler=soap&wsdl=1",array(
        "style"=>SOAP_RPC,
        "use"=>SOAP_ENCODED,
        "encoding"=>"UTF-8",
        "login"=>$userName,
        "password"=>$passwd,
        "trace"=>1,
       ));
$r=call_user_func_array(array($client,str_replace('.','_',$call['method'])),$call['params']);
/**
* Get result as XML String
**/
$req = $s->__getLastRequest();
```
